THE NORTH AMERICAN SPECIES OF THE GENUS LIMNOPHORA ROBINEAU-DESVOIDY, WITH DESCRIPTIONS OF NEW SPECIES (MUSCIDÆ, DIPTERA)

By H. C. Huckett Riverhead, N. Y.

INTRODUCTION

The genus Limnophora Robineau-Desvoidy comprises a large group of flies that are not familiar to collectors in North America except for their apparently uninteresting appearance. They are to be met with usually in the vicinity of water, especially along rivers and lakes, the immature forms presumably living an aquatic or semi-aquatic existence. On the other hand, the species belonging to the group Gymnodia Robineau-Desvoidy are commonly found near decay and filth, resembling the muscoid flies in habit.

The object of the present study is to bring together as completely as possible the records of species known to occur in North America with a view to facilitating their study and recognition. Numerous collections have been examined, and it is evident generally that there has been a considerable amount of misidentification, and that there are yet a number of species to be recorded. The fragmentary nature of the literature has also been a serious bar to further progress and interest.

The writer has had the privilege of examining the large faunal collections made by Dr. J. M. Aldrich in the Rocky Mountains and Alaska, by Dr. A. L. Melander, Mr. H. L. Seamans, and Mr. C. B. D. Garrett in the Rocky Mountains, by Mr. C. W. Johnson in the New England States, and by the late Professor J. S. Hine in Alaska.

The collections in the following institutions have been examined through the generous assistance of their keepers; the United States National Museum, Washington; Cornell Univer-

sity, Ithaca; the American Entomological Society, Philadelphia; the Boston Society of Natural History, Boston; the Canadian National Collection, Ottawa; the American Museum of Natural History, New York; the Field Museum, Chicago; and that of the Illinois State Natural History Survey, Urbana. I also have been privileged to examine the private collection of Dr. A. L. Melander, and of the late Professor J. S. Hine. Dr. E. P. Van Duzee has very kindly forwarded paratypic material from the collection of the California Academy of Sciences, San Francisco.

I wish also to acknowledge the valuable advice and information offered by Dr. J. M. Aldrich, Dr. O. A. Johannsen, Dr. J. Villeneuve, and Mr. E. Séguy concerning the nomenclatorial problem arising from the unsatisfactory status of the generic name Limnophora.

To Mr. O. Ringdahl I am deeply indebted for the invaluable help and advice proferred concerning the identification of subarctic forms. Much of the new material was sent to Mr. Ringdahl for examination and comparison with Scandinavian forms.

I have also had considerable help from Mr. J. E. Collin in the identification of species occurring in Baffin Land and Greenland. In addition Mr. Collin has very kindly made the necessary comparisons of North American material with Walker's types in the British Museum, thereby rendering it possible to establish once more the identity of these little known species.

Mr. Collin has provided me with a list of species that he has recognized as occurring in Greenland, many of which I have not had the opportunity of studying. A few of these species are included in the records that follow, having been sent to Mr. Collin for study. The remaining species are listed at the close of the paper. All of these species are included by Mr. Collin in a paper on the Greenland species of Limnophora that has recently been published in the Transactions of the Entomological Society of London (6a).

EXPLANATION OF TERMS USED IN KEYS AND DESCRIPTIONS

Every effort has been made to discover additional, tangible characters among species that are apparently difficult to distinguish under the best of circumstances. A few such have been grasped and used in the hope that they may be of some use in studies of a limited nature. Whether such characters will survive the test of wider application is entirely questionable.

The following explanations are offered with a view to aiding in the detection of little known characters that may be mentioned, to clarify the descriptive terminology used, and to assure a common understanding when making measurements.

Unless otherwise stated, the measurement between the eyes is taken at the narrowest distance of separation, which is usually at middle of frons; the breadth of parafacial is measured at base of antennæ when the head is viewed in profile; the height of cheek is taken at the narrowest distance between the margin of eye and the ventral border of head, at a point previous to the upward curvature of the head capsule defining the occipital and genal regions.

The oral margin is said to be protruded beyond the base of antennæ when projecting beyond a line drawn in a vertical plane from the most anterior part of parafacial. In other words, when the head is viewed in profile, the axis of the head capsule at a level with the oral margin is greater than that at a level with base of antennæ.

The mesonotum, unless otherwise stated, is viewed from above and in front.

The accessory bristles of the mesopleural series of bristles occur in the marked intermission between the dorsal and following bristles in the series. This interspace is bare in many species, and is filled by one or more weaker bristles in a few species, e.g., (Spiligona) aerea (Zetterstedt), novæ-angliæ Malloch, imitatrix (Malloch).

The scutellum of many species in the subgenus Spilogona Schnabl and Dziedzicki possesses one or more setulose hairs which are appressed and directed caudad. These hairs are situated on the dorsal margin of lateral declivities adjacent the apical bristles, e.g., (S.) aerea (Zetterstedt), rufiitibia Stein, obscuripennis Stein. On the other hand such scutellar hairs are not present in (S.)narina (Walker), alticola Malloch, torreyæ Johannsen, and suspecta Malloch.

The abdomen is viewed from above and behind unless otherwise stated.

The first visible tergum is designated as terga 1+2, the second as tergum three, the third as tergum four, and the fourth as tergum five.

The basal sclerite of hypopygium is situated immediately caudad of tergum five.

The veins of the wings have been named according to the system introduced by Comstock and Needham (7),* and is as follows:—

= Radius I.

First longitudinal vein

Second longitudinal vein = Radius 2+3.

Third longitudinal vein = Radius 4+5.

Fourth longitudinal vein = Media 1+2.

Fifth longitudinal vein = Media 3 plus Cubitus I.

Sixth longitudinal vein = Cubitus 1 plus first Anal.

Anterior cross vein = Radius—Media cross vein.

Posterior cross vein = Media—Cubitus cross vein.

Aricia Pandellé in part, Revue ent. France, 1899 XVIII p. 115. The genus Limnophora was erected by Robineau-Desvoidy (40) in 1830 for the reception of twenty nominal species, fourteen of which are European and none of which, according to Collin (5), have ever been recognized by subsequent authors. That the generic name is still in good use under these conditions exemplifies in a striking way the peculiar influence that tradition and expediency have exerted.

There have been three types designated for the genus. Robineau Desvoidy (40) himself did not indicate that any one of the original species might be taken as the type. The species palustris is used as a basis for comparative description for others that follow in the list, and on this account might be regarded as a typical species of the genus. But there the matter rests since Robineau-Desvoidy's material has never been examined.

In 1866 Rondani (42) designated Anthomyia compuncta Wiedemann as the type of Limnophora, a species not included in the original series by Robineau-Desvoidy. Rondani evidently followed Macquart's (23) prior list of 1835 inasmuch as he repeats the names of the few original species belonging to the genus before citing compuncta. He apparently did not recognize any of the former species to warrant a type designation from

¹ Villeneuve and Séguy have also assured me by correspondence that the original material has never been recognized as such, and so far as they know it is not in existence.

among them. Both Meade (33) and Osten Sacken (36) record the statement that *Anthomyia compuncta* Wied. is the type of Limnophora.

In 1910 Coquillet (12) designated Limnophora palustris Robineau-Devoidy as the type, the second species from the original series and the first of those recorded by Macquart and Rondani. It is very doubtful whether, under the circumstances, Coquillett had any definite knowledge regarding the identity of palustris. The most helpful opinion about the matter is given by Collin (5), who bases the appearance of the type on a comparison with the generic description. I can scarcely accept such an assumption regarding the identity of the species as proof of the genus.

In 1928 Karl (19) designated Musca notata Fallen² as the type of the restricted genus Limnophora of recent authors, which species thereby becomes the type of the genus Limnophora sens.-lat. However, as in the previous case of Rondani's designation, neither compuncta nor notata is included in the original series of species belonging to the genus, and hence their designation is invalid according to the rules of the International Committee on Nomenclature.

In conclusion, it may be said that in so far as a study of the literature reveals there has been no valid type designation that would fix the identity of the genus, largely, it is presumed, because none of the original species mentioned by Robineau-Desvoidy has been known to be available for study. Their existence appears to have ceased with the publication of their names. The permanent status of the generic name Limnophora will largely depend on fixing the type of the genus. It is to be hoped that whatever be the ultimate decision concerning the matter by fellow workers or by any authorized body due regard will be given to the feasibility of retaining the present generic name.

² Mr. Karl explains in a recent letter that the species denoted by him as "typische art" should be regarded as representative species for the group, his purpose being to suggest the name of well known species whereby students might be able the more readily to recognize the various groups. This did not necessarily involve the designation of the type species.

The genus Limnophora sens.-lat. contains numerous species from North America, many of which have been allotted to various genera at different times.

In 1835 Macquart (23) added nine European species to the original number, including compuncta Wiedemann and triangula Fallen of North American occurrence. The well known European species Musca notata Fallen was included by Macquart in his newly formed group Spilogaster. Schiner (44), Rondani (42), and Meade (34), followed Macquart's classification. but transferred the species triangula to the genus Cœnosia.

In 1889, 1890, and 1902, Schnabl (45) (46) (47), presented contributions concerning the limitations of certain allied groupings, in which he restricts the use of the generic name to certain species of which notata and triangula are representative. In the light of more recent work, it appears that Schnabl's concept regarding the limitations of the groups are well founded, although from his own diagnostic descriptions such is difficult to interpret. He introduces the use of the male genitalic characters to confirm the contention of Strobl that the species included by him in the new genus Pseudolimnophora (61) are more closely related to Limnophora than to Cœnosia, the commonly accepted genus at this time.

In 1911 Schnabl and Dziedzicki (49) produced their great work, *Die Anthomyiden*, in which the genus Limnophora is divided into seven subgenera, four of which occur in North America, namely, Limnophora sens.-str., Leucomelina Macquart, Brontæa Kowarz, and the new subgenus Spilogona. The classification of the group is based largely on the more or less arbitrary nature of the characters exhibited by the shape of the genitalic appendages in the male sex. No types are designated.

Meanwhile in 1899 Pandellé (37) had retained the old group name Aricia to include four subgenera, including Aricia, Spilogaster, and Limnophora. To the two former segregates he imparts the species notata Fallen and carbonella Zetterstedt respectively. It is evident in glancing through the list of species that Pandellé's treatment of the various categories embraced something much wider in its application than what is credited to such rankings as genus and subgenus today.

Stein (55) (56) (57) (58) (59) in all his contributions to the faunal studies of the world has regarded the genus in its broadest meaning, not recognizing many of the lesser segregates of Schnabl and Dziedzicki, nor the limnophorine genera of Rondani and Strobl. He follows the traditional treatment of the genus. reserving it for such species as possess the following combination of characters: Abdomen invariably marked by paired subtriangular areas, male genitalic appendages not prominent, thorax with two pairs of presutural dorsocentral bristles, and with the sternopleural bristles not arranged in an equilateral triangle, prealar bristle absent, antennæ with bare or finely pubescent arista, hind tibia with no bristles on posterodorsal surface. Ringdahl (39) has followed Stein in the treatment of the Swedish forms of Limnophora. This generic concept forms the basis for the present classification of the species from North America.

In 1918 and 1921 Malloch (26) (28) unintentionally redefined Schnabl and Dziedzicki's conception of the subgenus Limnophora, with possibly minor differences, raising the group to full generic rank. He based his conception of the genus on an entirely new set of delimiting characters. The large number of species formerly accredited to the genus he (28) placed under the generic name Melanochelia Rondani, a mistake for the name Spilogona, as later recognized by him (31).

In 1921 Collin (5), working independently, also redefined the segregates comprising the genus, using identically the same characters introduced by Malloch to restrict the group Limnophora, namely the presence of hairs along the lateral margins of prosternum and base of vein R. 4+5. In addition Collin attempted to fix the segregates by depicting the probable nature of palustris Robineau-Desvoidy, and by designating compuncta Wiedemann as the type of Spilogona. In treating of the European genera I have generally accepted the synonymy indicated by Collin.

Séguy (51) in 1923 and Karl (19) in 1928 used the characters adopted by Malloch and Collin to classify the species of Limnophora sens.-lat. occurring in France and Germany respectively.

There are four nominal genera described from North America which are closely related to the genus Limnophora.

In 1913 Malloch (25) described the genus Paralimnophora for the reception of the single new species, *P. brunnesquama* (=narina Walker), the specimens being taken in New Hampshire, New Brunswick, and Quebec. Stein (59) has pointed out that the generic name is preoccupied. There appear to be no characters of sufficient significance to warrant the separation of the genus from Spilogona.

In 1918 Malloch (26) introduced the new genus Bucephalomyia with the species *Tetramerinx femorata* Malloch as type.

In 1919 Aldrich (2) erected the genus Sphenomyia for the reception of the single new species, S. kincaidi, taken in Alaska. There are two species referable to this genus, kincaidi and biquadrata (Walker). The males resemble those of Spilogona leucogaster (Zetterstedt), differing generically in that the wing vein R. 4+5 has a few setulæ towards base.

In 1920 Malloch (27) described the two genera Eulimnophora and Lispoides, with the types Limnophora arcuata Stein and Limnophora acquifrons Stein respectively, both species being of wide distribution in North America. The former genus is now considered by Malloch (32) as a synonym of Gymnodia Robineau-Desvoidy.

I have refrained from including Schnabl's genus Limnospila (48), containing the single palearctic species L. albifrons (Zetterstedt), as a component part of Limnophora, despite the fact that the species naturally belongs to the Limnophorinæ rather than the Cænosiinæ, because I am not certain regarding the relationship of the genus to other genera, such as Tetramerinx Berg. Artificially the genus may be separated from Limnophora by the position of the sternopleural bristles, which are situated in the form of an equilateral triangle, as in Tetramerinx. I am inclined to believe that this single character can no longer serve the purpose of delimiting the Cænosiinæ from the Limnophorinæ.

The first formal attempt to list the North American species belonging to the genus Limnophora sens.-lat. was in 1878 when Osten Sacken published his catalogue of North American diptera. The family Anthomyiidæ contained largely the names of Walker's species from Canada and the United States, those of Loew's from North America, the determinations of material sent

by Professor Hagen of the Museum of Comparative Zoology, Cambridge, to Mr. Meade in England, and of records of species mentioned by Holmgren (15) as occurring in Greenland. There are eleven or twelve nominal species listed, which are scattered among the genera Aricia, Eriphia, Hylemyia, Limnophora, and Anthomyia.

In 1898 Stein (54), working on the collections of Hough, Aldrich, Johnson, and Nason, recorded six species of Limnophora, and in 1920 (60), with a second consignment of material from Aldrich, Johannsen, Bradley, and Melander before him, recognized eighteen additional species, and gave a key to twenty-one North American forms.

In 1905 Aldrich (1) published his catalogue of North American diptera, which not only incorporated the records of Osten Sacken, but also brought together the faunal lists of Slosson (52), Bigot (3), Williston (64), Coquillett (9), and Stein (54), besides the Mexican records of Giglio-Tos (15), and Van der Wulp (62). Excluding the Mexican species, there are seventeen species listed in Limnophora, one in Cœnosia, and three in Spilogaster, making a total of twenty-one species.

Iu 1921 Malloch (28) published his keys to the genera Melanochelia (Malloch not Rondani) and Limnophora sens.-str., recording therein many of the species described by him. In the former group there are twenty-four species included, whilst in the latter four.

More recently Johnson (18) has listed seventeen species from New England, included in the groups Lispoides, Limnophora, Spilogona, and Paralimnophora Malloch; and Leonard (21) has recorded fifteen species in the New York State list of insects.

In the following pages there are listed the records of eightyone species and two varietal forms. Mr. Collin (6a) has recorded
twelve additional species occurring in Greenland, which I have
not been able to examine; likewise there are the records of five
more species from North America which I am unable to verify
owing to the fact that the material has not been available for
study. In all there must be about one hundred species so far
recognized as occurring in North America.

Of the species that have been studied there are three in Limnophora; two in Pseudolimnophora; two in Sphenomyia; one in Buchephalomyia; one in Lispoides; three in Gymnodia; and sixty-eight species and two varieties in Spilogona. Of these, thirty-four constitute additional records for North America, and twenty-nine are described as new to science.

The restriction of the genus Limnophora Robineau-Desvoidy to a more specific grouping of the species was first attempted by Schnabl (45) in 1889, to be followed by further contributions on the problem in 1890 (46) and 1902 (47). In 1911 Schnabl and Dziedzicki (49) published their important work, *Die Anthomyiden*, in which the relationship of the various segregates of Limnophora is set forth at some length. The group concepts were largely based on a series of arbitrary characters of which that of the male genitalia formed an important contribution. Fifteen European species and one varietal form are included in the subgenus Limnophora, most of which had heretofore been recorded by authors in such genera as Limnophora sens.-lat., Spilogaster, Aricia, and Cœnosia. No type was designated for the new subgenus.

In 1918 and 1921 Malloch (28) redefined the group on the basis of an entirely new set of characters, restricting the group to those species with setulæ at base of vein R. 4+5, and with a series of hairs along lateral margins of prosternum. His concept of the group approaches that of Schnabl and Dziedzicki.

In 1921 Collin (5), working independently, used almost the same identical characters introduced by Malloch to classify the British species of Limnophora. He records Coquillett's prior

designation of *Limnophora palustris* Robineau-Desvoidy as type of the genus, and depicts the probable appearance of this species by a reference to the generic description of Robineau-Desvoidy.³ Séguy (51), with minor changes, followed Collin in the classification of the French species of Limnophora.

In 1928 Karl (19) designated the well known European species *Musca notata* Fallen as type of the subgenus Limnophora. This species conforms to the concept of the segregate as outlined by Schnabl and Dziedzicki, Malloch, and Collin according to Dr. J. M. Aldrich,⁴ but whether the species is conspecific with any of Robineau-Desvoidy's original species, including *palustris*, it is impossible to say definitely.⁵

In 1850 Macquart (24) established the genus Leucomelina, with the new Brazilian species Leucomelina pica as type. In his description of the genus Macquart drew attention to the character of vein M. 1+2, which he described as curved at apex, thus restricting the cell R. 5 at margin of wing. In 1885 Bigot (3) came to the conclusion that there was very little evidence for the retention of Macquart's genus, and favored its suppression and union with Limnophora sens.-lat. In 1893 and 1895 Giglio-Tos (13) described three additional Mexican species, and in 1896 Van der Wulp (62) revised the genus as restricted to Mexico, characterizing the genus as possessing the vein M. 1+2distinctly curved at apex, in contrast to the entirely straight vein in Limnophora. In 1911 Schnabl and Dziedzicki (49) maintained the group as a subgenus of Limnophora sens.-lat., separating it from Limnophora sens.-strat. by the distal curvature of vein M. 1+2. Stein (59), in listing the genera of the world, recorded the species of Leucomelina described by Macquart and Giglio-Tos among those of Limnophora sens.-lat.

Malloch (29), in re-examining Van Der Wulp's species, recognized the congeneric relationship between Leucomelina and Limnophora as restricted by him. He stated further that the Limnophora of Van Der Wulp contained three species that belong

³ I have already discussed the problem concerning the designation of not only this species but also that of *Musca notata* Fallen as types of Limnophora on page 29.

⁴ From an unpublished manuscript.

⁵ From correspondence with Dr. J. Villeneuve.

to Leucomelina, species which in common with many of those in Europe and North America have not the vein M. 1+2 curved forward at apex.

Numerous authors (44) (43) (34) (61) (37) have followed Macquart (23) in using the loosely constructed genus Spilogaster for the reception of one or more species of Limnophora sens.-lat., notably in the case of Musca notata Fallen. Westwood (63) has designated Musca quadrum Fabricius as the type of the genus, a species which has been included by recent European workers in the genus Helina Robineau-Desvoidy.

Diagnostic characters:—Wing with a few setulæ at base of vein R. 4+5; prosternum with a series of hairs along lateral margins; first abdominal sternum with no setulæ; hind tibia with apical anterodorsal bristle lacking.

Johnson (17) has considered *Leucomelina garrula* Giglio-Tos as a synonym of *narona*. I have only been able to see a female specimen of *garrula* that has been authentically named, and prefer to leave the matter open until more material is available.

The species is widely distributed throughout the North American continent, specimens having been seen from Mexico, Florida, and Texas; California, Washington, and Oregon; Illinois; New Jersey and New York; the New England States; and Canada. There is a considerable degree of variation according to the localities, but an examination of the genitalic appendages has failed to indicate any significant differences that might justify the separation of the specimens into more than one species.

In a series of specimens from the Okefenokee Swamps of Georgia, the vein M. 1+2 is very slightly curved at apex and the calyptræ are intensively infuscated. In occasional specimens there are only three pairs of postsutural dorsocentral bristles instead of the normal four pairs.

New Hampshire, 2 \, Franconia, \(—\) (Mrs. Slosson).

This species is almost coextensive with narona in its distribution, having been recorded from Florida and New Mexico; California, Oregon, and Washington; the Rocky Mountain States of Idaho, Montana, Wyoming, and Colorado, and the Canadian Province of Alberta; Illinois; New Jersey, New York, and New England.

I have a large series of specimens before me among which there are occasional specimens with three pairs of postsutural dorsocentral bristles instead of the normal four pairs. In isolated cases there is a slight indication that the vein M. 1+2 is curved at apex. In the males the distance separating the eyes across the frons varies considerably in extent. In none of the female specimens has the mid tibia a median anterodorsal bristle, though in a few specimens the fore tibia possesses a median posterior bristle.

Limnophora (Limnophora) groenlandica Malloch

Limnophora groenlandica Malloch, Trans. Amer. Ent. Soc., 1920 XLVI No. 802 p. 147.—Malloch, Canad. Ent., 1921 LIII p. 64.

The species is recorded from Greenland, being represented only by the female sex. As indicated by Malloch's description and key, the female very closely resembles that of *discreta*.

Subgenus Pseudolimnophora Strobl

Naturforsch., 1911 XCV Nr. 2 p. 152.—Stein, Arch. f. Naturgesch., 1914 (1913) Abt. A Heft 8 pp. 27 . 28.—Stein, Arch. f. Naturgesch., 1916 (1915) Abt. A Heft 10 pp. 83 . 111.—Ringdahl, Ent. Tidskr., 1918 XXXIX Heft 2 p. 160.—Stein, Arch. f. Naturgesch., 1920 (1918) Abt. A Heft 9 pp. 46–47.—Séguy, Faune de France, Part VI 1923 p. 199.

The genus Pseudolimnophora was erected by Strobl (61) in 1894 for the reception of six nominal species. Later in the same year Pokorny (38) described the genus Stroblia, an arbitrary change of name for Pseudolimnophora. Pokorny included in this genus the original species listed by Strobl, including triangula Fallen and Limnospila albifrons Zetterstedt (= obscuripes Rondani) of North American occurrence. In 1901 Coquillett (11) designated Musca triangula Fallen, the first species of the original series, as the type of Pseudolimnophora. In 1921 Collin (5) maintained the group as a subgenus of Limnophora sens.-lat., indicating its relationship to Limnophora sens.-str. through the possession of a few setulæ at base of vein R. 4+5 and the presence of a series of hairs on lateral margins of prosternum.

The species belonging to this group were included in the genus Cœnosia by earlier European authors, no doubt on account of the widely separated eyes and the strongly developed vertical and ocellar bristles in the male. Later workers transferred the

species triangula, albifrons, and nigripes to the genus Limnophora sens.-lat., chiefly on account of the markings and structure of the abdomen.

Diagnostic characters:—Wing vein R. 4+5 with a few setulæ at base; prosternum with a series of setulæ along lateral margins; first abdominal sternum with setulæ; hind tibia with apical anterodorsal bristle lacking; eyes in male as widely separated as in female.

I am of the opinion that all the above specimens represent a single species despite a marked degree of variation, notably in the number of postsutural dorsocentral bristles and in the bristling of the mid tibia. Three male specimens from Alaska and one from British Columbia have three pairs of postsutural dorsocentral bristles, and five males and one female specimen from Alaska have four postsutural dorsocentral bristles on one side and three on the other, the so-called second bristle being very weak. The mid tibia possesses one to three posterior bristles, the number frequently varying in a single specimen.

A second species belonging to the group, namely triangula Fallen, has been recorded by Lundbeck (22) as occurring in Greenland. This species is distinguished in part from nigripes by the presence of three pairs of postsutural dorsocentral bristles, and by having one posterior bristle on mid tibia, characters which I am unable to appraise correctly owing to the variation shown by the above specimens.

Stroblia triangula Pokorny, Verh. zool.-bot. Ges. Wien, 1894 (1893) XLIII p. 541.

Aricia (Limnophora) triangula Pandellé, Revue ent. France, 1899 XVIII p. 131.

Limnophora (Pseudolimnophora) triangula Collin, Ent. Month. Mag., 1921 ser. 3 VII p. 242.—Karl, Tierwelt Deutschlands, Th. XIII 1928 p. 94.

This species has been recorded by Lundbeck (22) from Greenland. According to many European authors the species may be separated from *nigripes* by the possession of only three pairs of postsutural dorsocentral bristles. Among the specimens recorded as *nigripes* there are a few with three pairs of postsutural dorsocentral bristles, but I am of the opinion that this number represents a variation within the species rather than a specific character.

There is apparently a considerable degree of confusion in the literature concerning the identity of the species. Stein (56) in 1907 listed nigripes Robineau-Desvoidy as a synonym of triangula Fallen, and $C\alpha nosia$ triangula of Rondani as a synonym of pacifica Schiner not Meigen (= pollinifrons Stein). Strobl (61) in 1894 listed $C\alpha nosia$ nigripes Macquart not Robineau-Desvoidy as a synonym of triangula Fallen. In 1916 Stein (58) recognized nigripes Robineau-Desvoidy and triangula Fallen as distinct species.

Subgenus Sphenomyia Aldrich

Sphenomyia Aldrich, Proc. Ent. Soc. Wash., 1919 XXI No. 5 p. 108.—Seamans, Canad. Ent., 1926 LVIII p. 175.

The genus Sphenomyia was described by Aldrich (2) in 1919 for the reception of one species, kincaidi new. In 1926 Seamans (50) added another species to the genus, banffi new. In general characteristics this group is much more closely allied to those lacking the setulæ at base of vein R. 4+5 than to those possessing such.

Diagnostic characters:—Wing vein R. 4+5 with setulæ towards base; prosternum with no series of setulæ along lateral margins; hind tibia with an apical anterodorsal bristle; frontal vitta with a black polished triangular area, small and confined to the vicinity of ocellar triangle in male, large and extending to base of antennæ in female; sternopleural pristles arranged 1:1.

KEY TO FEMALES

- 1. Halteres yellowish, at most tinged with purple; ovipositor very much flattened laterallybiquadrata Walker
- Halteres black; ovipositor not markedly flattened laterally.

kincaidi Aldrich

Limnophora (Sphenomyia) biquadrata (Walker)

Eriphia biquadrata Walker, List Dipt. Brit. Mus., 1849 (1848)
IV p. 963.—Osten Sacken, Misc. Coll. Smithsn. Inst., 1878 III
p. 167.—Aldrich, Misc. Coll. Smithsn. Inst., 1905 XLVI No. 1444 p. 535.

Limnophora biquadrata Stein, Zeitschr. f. Hymen, u. Dipt., 1901 I Heft 4 p. 189.—Aldrich, Misc. Coll. Smithsn. Inst., 1905 XLVI No. 1444 p. 546.—Stein, Arch. f. Naturgesch., 1919 (1917) Abt. A Heft 1 p. 134.

Sphenomyia banffi Seamans, Canad. Ent., 1926 LVIII p. 175.

Male: Head with parafrontals and parafacials silvery pruinescent, cheeks less highly so; frontal vitta black with trace of whitish pruinescence; antennæ and palpi black, third antennal segment with trace of pruinescence; frontal triangle and proboscis polished. Thorax entirely black, shining, with trace of brownish pruinescence. Abdomen with terga 1+2 largely blackened, dorsum of terga 3, 4, and 5 silvery pruinescent, terga 3 only with a pair of black subquadrate marks. Ventral surface of abdomen blackish subshining. Legs black. Wings hyaline; calyptræ whitish with yellow margins; halteres yellowish brown, tinged with purple.

Eyes large, with a few hairs, separated by a distance equal to that between posterior ocelli; frontal vitta gradually narrowed caudad to lineal dimensions; parafrontal bristles continued in series caudad to level of frontal triangle; parafacials, at base of antennæ, and cheeks narrower than breadth of third antennal segment; bristles and setulæ confined to ventral border of cheeks; arista minutely pubescent. Thorax with numerous fine setulæ; acrosticals setulose; postsutural dorsocentral bristles four pairs; scutellum with a few setulose hairs on lateral declivities; mesopleural series of bristles with an intermediate predorsal bristle; sternopleural bristles, 1:1.

Abdomen ovate, depressed; tergum 3 with a pair of narrowly separated subquadrate marks, restricted to mesal third of tergum; terga 4 and 5 unmarked; sternum 5 with a few fine setulæ, and with 2 or 3 fine bristles towards apex or processes.

Fore tibia with no posterior median bristle; mid femur with a series of weak bristles on proximal half of anteroventral surface, and a series of longish bristles on proximal half of posteroventral surface; mid tibia with 2 posterior bristles; hind femur with 3 or 4 bristles on distal half of anteroventral surface, with no bristles on proximal half of posteroventral surface; hind tibia with 1 or 2 anteroventral, 2 or 3 anterodorsal, and 1 or 2 weaker posterior bristles.

Wings with costal thorns small; veins R. 4+5 and M. 1+2 gradually divergent toward wing margin. Length, 5.25 mm. Records:—

British Columbia, 1 &, Oliver, April 27, 1923; 1 &, May 28, 1923. (C. B. D. Garrett)

Alberta, 1 \, Banff, June 16, 1922. (C. B. D. Garrett)

Wyoming, 1 ♀, Canyon Camp, Yellowstone Park, Aug. 12, 1918. (A. L. Melander)

Manitoba, 1 &, 1 \, Victoria Beach, Aug. 8, 1926. (G. S. Brooks) 1 \, Stony Mountain, Aug. 9, 1923. (J. B. Wallis) Ontario, 1 \, Macdiarmid, Lake Nipigon, June 11, 1922; 1 \, 2,

Lake Abitibi, Low Bush, June 10, 1925. (N. K. Bigelow) 1 &, Ottawa —.

I feel confident that the above males and females are conspecific, despite the fact that they exhibit a marked case of

sexual dimorphism. The male of biquadrata has a silvery pruinescent abdomen, whereas in the female the abdomen is entirely black and highly shining. A male specimen was sent to Mr. J. E. Collin for comparison with Walker's type in the British Museum, who reported that, in his opinion, the specimens were identical.

Limnophora (Sphenomyia) kincaidi (Aldrich)

Sphenomyia kincaidi Aldrich, Proc. Entom. Soc. Wash., 1919 XXI No. 5 p. 108.

RECORDS:-

Alaska, 1 9, Bering Sea, July, 1913. (F. Johansen)

The females of *kincaidi* may be readily distinguished from those of *biquadrata* by having the halteres blackened and not yellowish. In both species the ovipositor is armed with coarse spinules on anal plates, the scutellum has a number of setulose hairs on lateral declivities, and the mesopleural series of bristles possesses an intermediate predorsal bristle.

Subgenus Bucephalomyia Malloch

Bucephalomyia Malloch, Trans. Amer. Ent. Soc., 1918 XLIV No. 782 p. 273.

The genus Bucephalomyia was proposed by Malloch (26) in 1918 for the reception of one species, Tetramerinx femorata Malloch. The genus is allied to Pseudolimnophora in that the vein R. 4+5 has a few setulæ at base, the abdomen has broad subtriangular marks, the legs are weakly and sparsely bristled, and the eyes in the male are broadly separated. However in Pseudolimnophora the prosternum has a series of setulose hairs along lateral margins, whereas in Bucephalomyia the prosternum is bare.

Diagnostic characters:—Vein R. 4+5 of wing with setulæ toward base; prosternum with no series of setulose hairs along lateral margins; first abdominal sternum bare; frontal vitta pollinose, with no polished frontal triangle; hind tibia with no apical anterodorsal bristle; sternopleural bristles arranged 1:2.

Limnophora (Bucephalomyia) femorata (Malloch)

Tetramerinx femorata Malloch, Proc. U. S. Nat. Mus., 1913 XLV No. 2004 p. 603.—Malloch, Canad. Ent., 1917 XLIX p. 226. Bucephalomyia femorata Malloch, Trans. Amer. Ent. Soc., 1918 XLIV No. 782 p. 273.

Limnophora femorata Stein, Arch. f. Naturgesch., 1919 (1917) Abt. A Heft 1 p. 135.

This species has been recorded from Los Angeles, California, and from Alamogordo, New Mexico, and constitutes the sole representative of the subgenus. The species, except for the characteristic triangular markings on the abdomen, is strikingly different from those of other subgenera belonging to *Limnophora sens. lat.*, resembling in many respects those species found in such associated genera as Tetramerinx, Phyllogaster, or Pseudocœnosia.

The head in male and female is dichoptic, with silvery pruinescence, the antennæ and arista are elongated, tachinidlike, the ocellar and vertical bristles in both sexes are robust, the oral margin is not produced; the legs are weakly and sparsely bristled, and the hind tibia lacks the apical anterodorsal bristle. Further, in the male the hind coxæ have each two stubby spines at apex (ventrad), whilst in the female the mid coxæ have each a stout recurved spine; in the male the hind femur has a fasciculus of short spines at base of ventral surface which is absent in the female; the anal plates of ovipositor possess setulose hairs only.

Subgenus Lispoides Malloch

Lispoides Malloch, Trans. Amer. Ent. Soc., 1920 XLVI No. 802 p. 146.—Malloch, Canad. Ent., 1921 LIII p. 61.

The genus Lispoides was erected by Malloch (27) in 1920 for the reception of a single species, *Limnophora aequifrons* Stein. The subgenus differs essentially from its allies in that the parafrontal setulæ are continued ventrad onto the dorsal region of parafacials.

Diagnostic characters:—Wing vein R. 4+5 with no setulæ toward base; prosternum with no series of setulæ on lateral margins; first abdominal sternum hairy; dorsal half of parafacials clothed with a few setulose hairs.

Quebec, 1 9, St. Chrysostome, June 28, 1917. (G. S. Walley)

The species is undoubtedly present in nearly all parts of North America. It is commonly to be found on the rocks of rivers and streams. The head of the male and female are very similar in structure and vestiture, the eyes being separated by a distance slightly less than that between the oral vibrissæ. In addition, the species may be readily separated from those which possess widely separated eyes in the male by the presence of setulose hairs on the dorsal half of parafacials.

Subgenus Gymnodia Robineau-Desvoidy

In 1863 Robineau-Desvoidy described the genus Gymnodia for the reception of the single species *pratensis*, new, which has been regarded by subsequent authors as the type of the genus. It was early accepted that *Gymnodia pratensis* was a synonym of *Anthomyia polystigma* Meigen, a species listed by Macquart (23) in 1835 as belonging to the genus Limnophora sens.-lat. On account of the distal curvature of the wing vein M. 1+2 in the type, the genus Gymnodia was associated by both Robineau-Desvoidy and Pandellé (41) (37) with such muscoid genera as Graphomyia, Muscina, and Stomoxys. Stein (56) in his catalog of palaearctic diptera recorded the genus as interpreted by Pandellé among the "genera dubia," although earlier in the same work he had listed Robineau-Desvoidy's genus among the synonyms of Limnophora.

In later years, Collin (5), followed by Séguy (51) and Karl (19), has redefined the genus, maintaining its association with closely allied groups as subgenera of the genus Limnophora sens.-lat.

In 1873 Kowarz (20) erected the genus Brontæa with *polystigma* Meigen as type. If the synonymy of *pratensis* with *polystigma* be accepted, then Brontæa becomes an absolute synonym of Gymnodia.

In 1881 Meade (34) included the species polystigma together with other British species of Limnophora sens.-lat. in the genus Spilogaster.

In 1911 Schnabl and Dziedzicki (49) maintained the identity of Brontæa as a valid subgenus of Limnophora, whilst Stein and other European authors continued to regard the genus of doubtful rank, merging its identity with that of Limnophora.

In 1920 Malloch (27) described the North American genus Eulimnophora, designating *Limnophora arcuata* Stein as the type. There are apparently no satisfactory reasons for maintaining the separate identity of this genus and *Gymnodia*, the generic characters being almost identical.

There are three species belonging to this segregate that have been recognized as occurring in North America; two of them are known to inhabit filth, resembling the common house fly in this respect. According to Malloch (30) the group is better represented in Africa.

Diagnostic characters:—Wing vein R. 4+5 with no setulæ at base; prosternum with no series of hairs along lateral margins; parafrontal setulæ not descending onto parafacials to a level below that of base of third antennal segment; eyes ab-

normally large and expansive, restricting the parafrontals and parafacials to lineal dimensions when viewed in profile; in North American species the anterior intraalar bristle is weakly developed, sometimes absent, never longer than caudal pair of acrostical bristles; and the abdominal marks are arcuate in outline; the hind tibiæ have the apical anterodorsal bristle absent.

KEY TO SPECIES

- 1. Palpi and tibiæ largely yellowish; thorax with three or more strongly marked vittædebilis Williston
- Palpi and tibiæ largely black; thorax with vittæ more or less suffused and not sharply defined _____2

Limnophora (Gymnodia) debilis Williston

Limnophora debilis Williston, Trans. Ent. Soc. London, 1896 III p. 369.—Aldrich, Misc. Coll. Smithsn. Inst., 1905 XLVI No. 1444 p. 547.

Eulimnophora dorsovittata Malloch, Trans. Amer. Ent. Soc., 1920 XLVI No. 802 p. 146.—Malloch, Canad. Ent., 1921 LIII p. 12.—Frison, Bull. Ill. Nat. Hist. Surv., 1927 XVI Art. 4 p. 199.

Records:-

1 Q, Dallas, Texas, Sept. 17, 1907; 1 &, Sept. 18, 1907; 2 &, Sept. 19, 1907, bred from cow manure (F. C. Pratt). 1 Q, Biscayne Bay, Florida (A. T. Slosson).

The species is evidently well represented in the countries adjoining the Gulf of Mexico, being recorded from Jamaica, Porto Rico, and St. Vincent, in addition to the above North American records.

I can find no difference that would justify the separation of dorsovittata and debilis as distinct species. In the above series there is a considerable degree of variation in the color of the abdomen from grayish to entirely yellow depending, evidently, on

the developmental condition of the adults when captured. In the more teneral specimens the color has a tendency to yellowish.

Limnophora (Gymnodia) arcuata Stein

Limnophora arcuata Stein, Berl. Ent. Zeitschr., 1898 (1897) XLII Heft 3 and 4 p. 201.—Coquillett, Proc. U. S. Nat. Mus., 1900 XXII No. 1198 p. 256.—Howard, Proc. Wash. Acad. Sci., 1900 II p. 582.—Stein, Ann. Mus. Nat. Hungarici, 1904 II p. 469.—Aldrich, Misc. Coll. Smithsn. Inst., 1905 XLVI No. 1444 p. 546.—Smith, Ann. Rept. N. J. State Museum 1909, 1910 p. 791.—Stein, Arch. f. Naturgesch., 1911 Abt. A Heft I p. 135.—Johnson, Bull. Amer. Mus. Nat. Hist., 1913 XXXII Art. 3 p. 76.—Stein, Arch. f. Naturgesch., 1919 (1917) Abt. A Heft 1 p. 133.—Stein, Arch. f. Naturgesch., 1920 (1918) Abt. A Heft 9 p. 48, 56.

Eulimnophora arcuata Malloch, Trans. Amer. Ent. Soc., 1920
XLVI No. 802 p. 145.—Malloch, Canad. Ent., 1921 LIII p. 12.
Spilogona (Gymnodia) arcuata Huckett, Mem. 101 N. Y. (Cornell) Agric. Exp. Station, 1928 (1926) p. 834.

RECORDS:-

1 Q, Riverhead, New York, August 7, 1925; 1 Q, August 8, 1927; 1 Q, De Witt, Mitchell Co., Ga., July 23, 1912 (M. D. Leonard); 1 Q, Gainesville, Tex., May 15, 1923 (E. E. Russell).

The species is widely distributed throughout North America. Howard (16) includes the species among those flies that are commonly found associated with filth and manure, and hence capable of contaminating human food by their presence.

Limnophora (Gymnodia) cilifera (Malloch)

Eulimnophora cilifera Malloch, Trans. Amer. Ent. Soc., 1920 XLVI No. 802 p. 145.—Malloch, Canad. Ent., 1921 LIII p. 12. —Frison, Bull. Ill. Nat. Hist. Surv., 1927 XVI Art. 4 p. 198. RECORDS:—

1 &, Atherton, Missouri, Oct.; 1 &, Aug. —; 5 &, Columbus, Ohio, April 10 (J. S. Hine).

The species is smaller than either debilis or arcuata, rarely exceeding four millimeters in length. The females of cilifera and

arcuata are not readily distinguished structurally. In the former species the hind femur has a uniform series of short bristly hairs on proximal half of anteroventral surface, which is lacking in arcuata.

Subgenus Spilogona Schnabl and Dziedzicki

A Heft 10 p. 83.—Johannsen, Trans. Amer. Ent. Soc., 1916 XLII No. 756 p. 391.—Ringdahl, Ent. Tidskr., 1918 XXXIX p. 158.—Stein, Arch. f. Naturgesch., 1919 (1917) Abt. A Heft 1 p. 133.—Stein, Arch. f. Naturgesch., 1920 (1918) Abt. A Heft 9 p. 46.—Malloch, Trans. Amer. Ent. Soc., 1920 XLVI No. 802 p. 147.

Melanochelia Malloch not Rondani, Canad. Ent., 1921 LIII p. 61. In 1911 Schnabl and Dziedzicki (49) proposed the subgenus Spilogona as one of seven subgenera comprising the genus Limnophora sens.-lat. The new group contained nineteen European species, most of which had been recorded previously in such genera as Aricia, Anthomyia, Spilogaster, and Limnophora of authors.

The species belonging to Spilogona are separated from those of Limnophora according to Schnabl and Dziedzicki on the basis of a number of arbitrary characters which are difficult to evaluate, such as the degree of development of the bristles of the legs, the extent of convergence or divergence of veins R. 4+5 and M. 1+2, and the structure of the male genitalia. It remained for later workers to exploit the full significance of such conceptions. Mal-

loch (26) in 1918 had found a new combination of characters for splitting the old genus Limnophora into at least two parts, but was hesitant in naming them owing to the apparently uncertain status of many of the European segregates. His conception of the group, except for minor differences, approached that of Schnabl and Dziedzicki, although he misnamed the group Melanochelia Rondani, a nomenclatorial error corrected by him later (28) (31). Collin (5) in 1921, working independently, introduced the same characters used by Malloch to realign the component parts of Limnophora sens.-lat. According to these characters Spilogona belongs to the division of Limnophora sens.-lat. having no setulæ at base of vein R, 4+5, and no series of hairs along the lateral margins of prosternum. He, further, designated the fourth species of the original series, namely, Anthomyia compuncta Wiedemann, as the type of Spilogona. Séguy (51) in 1923 and Karl (19) in 1928 adopted Collin's classification of Limnophora, with but minor differences, in compiling a list of the species occurring in France and Germany respectively. Karl incidentally proposed the species Musca dispar Fallen as type of Spilogona,* a proposal which I am unable to accept on account of Collin's (5) prior designation of compuncta.

Stein (58) and Ringdahl (39) evidently recognized that there was some justification for the recognition of certain of the segregates comprising the genus Limnophora sens.-lat., but there is no evidence that they were aware of the full import of such characters as introduced by Malloch and Collin. Hence the segregate Spilogona was not recognized by these authors, no doubt partly owing to the inadequacy of the characters cited by Schnabl and Dziedzicki in defining the group.

Malloch (25) in 1913 proposed the genus Paralimnophora for the reception of narina Walker (= brunnesquama Malloch), basing his genus on the widely separated eyes and abnormally stout vertical and ocellar bristles on the head of the male. Stein (59) in 1919 pointed out that Paralimnophora was preoccupied in nomenclature, and placed Malloch's species in Limnophora. Malloch (28) in his key to Melanochelia (Malloch not Rondani)

^{*} See footnote on page 37.

included the same species under the name *velutina* (*brunnes-quama* preoc.). I am doubtful whether the genus is entitled to full recognition, and prefer to merge it for the present with Spilogona, as already indicated by Malloch himself (28).

The subgenus Spilogona contains by far the greatest number of species of any of the groups included in this study. The species are to be found in greatest abundance in the Canadian and subarctic life zones, descending through North America by way of the mountain ranges. In comparison, the species belonging to Limnophora sens.-str. and to Gymnodia are comparatively numerous in the tropical and subtropical zones whilst those of Spilogona are evidently fewer.

In structure Spilogona is most closely allied to Gymnodia, differing essentially from the latter group in having the frons, parafacials, and cheeks relatively well developed, not constricted to lineal proportions by the abnormal size of the eyes, and, in the North American species, by the markings on the abdomen being subtriangular or trapezoidal in shape, not arcuate.

Diagnostic characters:—Wings with no setulæ at base of vein $R.\ 4+5$: prosternum with no series of hairs along lateral margins: parafacials at base of antennæ with no setulose hairs descending to a level below that of base of third antennal segment: cheeks well developed, not constricted, usually higher than breadth of parafacials at base of antennæ: abdominal markings, if present, not arcuate in outline, usually trapezoidal, spherical, or subtriangular in outline.

KEY TO SPECIES

Males

	Mid tibia with no median ventral bristles9
4.	Oral margin when viewed in profile, protruded slightly beyond a level
	with base of antenna5
_	Oral margin, when viewed in profile, not protruded beyond a level with
	base of antenna6
5.	Scutellum with no appressed setulæ on dorsal margin of lateral declivi-
	ties adjacent the apical bristles; halteres yellowish to brownish; fore
	tibia with no median posterior bristle; sternopleural bristles, 1: 1.
	subrostrata Stein
_	Scutellum with appressed setulæ on dorsal margin of lateral declivities
	adjacent the apical bristles; halteres black; fore tibia with a median
	posterior bristle; sternopleural bristles, 1: 2hyperborea Boheman
6.	Halteres tinged with black; abdomen entirely blackish opaque7
	Halteres deep yellow; abdomen with more or less grayish pruinescence
	on terga, subshining
7.	Hind femur with a series of short bristles on basal half of postero-
	ventral surface; parafrontals with a pair of short bristles situated
	nearly on a level with anterior ocellus; frontal triangle opaque, not
	highly polishedobsoleta Malloch
_	Hind femur with no bristles on proximal half of posteroventral sur-
	face; parafrontals with no pair of weak bristles situated nearly on
	a level with anterior ocellus; frontal triangle glossy and polished.
	melanosoma, n. sp.
8.	Hind femur with a proximal series of longish posteroventral bristles;
	with the anteroventral series of bristles continued to base of femur;
	notopleural callosity with setulænovæ-angliæ Malloch
_	Hind femur with no series of longish bristles on proximal half of
	posteroventral surface; with the anteroventral series of bristles con-
	fined to distal half of femur; notopleural callosity with no setulæ.
	sectata, n.sp.
9.	Mid femur with a single stout spinelike bristle at base of ventral sur-
	face10
	Mid femur without stout spinelike bristle at base of ventral surface,
	with or without the usual series of two or more posteroventral
	bristles
10.	Processes of fifth sternum glossy at apex, highly polished; halteres
	blackish; mesonotum bluish gray, with trace of brownish median vitta
	caudad of transverse suturemonacantha Collin
_	Processes of fifth sternum not glossy nor highly polished at apex;
	halteres yellowish to brownish; mesonotum blackish or cinere-
	ous
11.	Parafacials at base of antennæ narrower than breadth of third an-
	tennal segment; mesonotum largely blackened, at most with trace of
	vittæ on presutural area; eyes separated by a distance not greater
	than that between posterior ocelli; costal thorn small 12
	Parafacials at base of antennæ as broad as breadth of third antennal

	segment; mesonotum grayish pruinescent, with seal brown infusca-
	tion, with 3 to 5 brownish vittæ on postsutural area; eyes separated
	by a distance at least as great as that between posterior ocelli; costal
	thorn robustsospita, n. sp.
12.	2 , 1
	tibia with no anterodorsal bristles; abdominal marks on terga 3 and
	4 expansive, extending to ventral surfaceinstans, n. sp.
	Parafrontals separated caudad by a lineal frontal vitta; mid tibia with
	1 or 2 short anterodorsal bristles; abdominal markings on terga 3
	and 4 confined to dorsum semiglobosa Ringdahl
13.	Halteres normally blackish14
	Halteres normally yellowish34
14.	Processes of fifth sternum clothed with a dense mat of fine spinules
1.1.	along inner bordersetilamellata, n. sp.
	Processes of fifth sternum with sparsely set setulæ or fine bristles on
	inner border15
15.	Oral margin protruded beyond a level with base of antenna
	Oral margin not protruded beyond a level with base of antenna20
16.	Large grayish species, 8 mm.; head buccate (as in Hammomyia) with
	parafacials broader than length of third antennal segment.
	tendipes Malloch
	Species not exceeding 7 mm, in length; parafacials not as broad as
	length of third antennal segment; eyes separated by a distance less
	than length of third antennal segment17
17.	Scutellum with setulose, appressed hairs on dorsal margin of lateral
	declivities adjacent the apical bristles; mesopleural series of bristles
	with an intermediate predorsal bristle; abdomen brownish black,
	shining, with no markings; parafacials at base of antennæ narrower
	than breadth of third antennal segmentalmquistii Holmgren
	Scutellum with no setulose hairs on dorsal margin of lateral declivities
	adjacent the apical bristles; mesopleural series of bristles with no
	intermediate predorsal bristle; abdomen with distinct grayish prui-
	nescence and blackish marks; parafacials at base of antennæ as
	broad as width of third antennal segment18
18.	Mesonotum with pale grayish pruinescence, and with five well marked
	black vittæ, the laterals foreshortened; cerci elongate, produced as a
	narrow polished, chitinous lamellasanctipauli Malloch
	Mosonotum largely blackish, with at most a trace of vitte on pre-
	sutural area; cerci not elongated, the apex extended as two slender,
	short styli
10-	v
18a.	Scutellum and presutural area of mesonotum sparsely setulose, the pre-
	sutural acrosticals in two distinct series; mesopleura with pale gray-
	ish pruinescencemegastoma Boheman
-	Scutellum and presutural area of mesonotum densely setulose, the pre-
	sutural acrosticals indistinguishable from the adjacent setulæ; meso-
	pleura entirely blackened19

19.	Eyes with a few hairs; mid tibia with no anterodorsal bristle.
	tristiola Zetterstedt
	Eyes bare; mid tibia with 1 or 2 anterodorsal bristles.
	extensa Malloch
20.	Presutural acrosticals stouter developed than the adjacent setulæ; fore
	tibia with a strong apical posteroventral bristle; hind tibia with the
	distal bristle of anterodorsal series stouter developed than the proxi-
	mal bristle; abdomen with widely separated dorsal markings, between
	which there are traces of a dorsocentral vitta21
	Presutural acrosticals setulose; fore tibia with a weak apical postero-
	ventral bristle; hind tibia with anterodorsal bristles not noticeably
	unevenly developed, or the distal bristle of series weaker developed
	than the proximal bristle; abdomen with markings fused or narrowly
	separated, and with no apparent dorsocentral vitta 22
21.	Eyes separated by a distance less than that between posterior ocelli in-
	clusive; parafrontals contiguous cephalad of anterior ocellus; abdo-
	men stoutly developed, short; abdominal markings sharply defined,
	broadly subtriangular; calyptræ whitefatima, n. sp.
_	Eyes separated by a distance exceeding that between posterior ocelli;
	parafrontals noticeably, though narrowly, separated cephalad of anterior ocellus; abdomen conical; abdominal markings ill defined,
	narrowly subtriangular; calyptræ yellowish tinged.
	tetrachæta Malloch
22.	Scutellum with a few setulose hairs on dorsal margin of lateral declivi-
	ties adjacent apical bristles23
	Scutellum with no such hairs on dorsal margin of lateral declivities
	adjacent apical bristles29
23.	Calyptræ entirely blackish brown, concolorous with halteres; abdomen
	entirely blackish, with no markings on tergaconcolor Stein
	Calyptræ whitish in contrast to color of halteres; abdomen with mark-
	ings on terga24
24.	Terga 3, 4, and 5 densely whitish pruinescent, with a pair of subquad-
	rate marks on tergum 3 only; eyes sparsely haired; halteres fuscous.
	leucogaster Zetterstedt
—	Terga 3, 4, and 5 with grayish pruinescence, and with markings on ter-
	gum 4 as well as on tergum 325
25.	Hind femur with a series of longish weak bristles on proximal half of
	posteroventral surface, the anteroventral series of bristles continued
	to base of femur obscuripennis Stein
_	Hind femur with no series of bristles on proximal half of posteroven- tral surface, at most with 1 or 2 isolated bristles; anteroventral series
	of bristles confined to distal half of femur
26.	Mesopleural series of bristles with one or more weaker intermediate
20.	predorsal bristles 27
	Mesopleural series of bristles with no such predorsal bristles 28
	25 predict of bristics with no such predictal bristics

27. Abdomen broadly ovate, depressed; hind tibia with one robust anterodorsal bristle situated at middle of tibia; basal sclerite of hypopygium with bristles scattered in a transverse series......pusilla, n. sp. Abdomen cylindrical or conical, not flattened dorsoventrally; hind tibia with 2 or 3 anterodorsal bristles; basal sclerite of hypopygium restricted, the bristles appearing tufted......denudata Holmgren Abdomen with markings on tergum 3 distinctly though narrowly sepa-28. rated, those on tergum 4 reduced in area, the surface largely densely whitish gray pruinescent; halteres black......addicta, n. sp. Abdomen with markings on tergum 3 fused across the dorsum, or, obscurely divided at middle, those on tergum 4 well developed, the tergal surface subshining, with dark reflections; halteres brownish. ærea Zetterstedt 29. Hind femur with no series of bristles on proximal half of posteroventral surface; sternopleura clothed on ventral surface with a tuft of abnormally stiff bristlespulvicrura, n. sp. Hind femur with a series of two or more bristles on proximal half of posteroventral surface30 30. Wings densely infuscated, blackened basad; abdominal markings on terga 3 and 4 confined to dorsum, their length longer than their greatest widthcarbonella Zetterstedt Wings hyaline or at most with traces of infuscation; abdominal markings on terga 3 and 4 broadly expanding caudad to reach the ventral surface, their length shorter than their greatest width......31 31. Eyes widely separated, frontal vitta as broad immediately cephalad of anterior ocellus as at base of antennæ; vibrissal area clothed with numerous, short coarse setulæ; ocellar triangle pollinose; hind tibia with apical anterodorsal bristle well developed, equivalent in length to apical anteroventral bristlenobilis Stein Eyes separated narrowly, frontal vitta not as broad immediately cephalad of anterior ocellus as at base of antennæ; vibrissal angle clothed with numerous fine, longish setulæ; frontal triangle highly polished; hind tibia with apical anterodorsal bristle setulose......32 32. Eyes with numerous hairs; parafrontal bristles continued in series caudad to a level with anterior ocellus; bucce with dense, fine, upcurved setulæ; mesonotum largely deep blackish; calyptræ and wings clear, hyalinealberta, n. sp. Eyes bare, or at most with hairs very sparse; parafrontal bristles not continued in series to a level with anterior ocellus; buccæ almost devoid of setulæ, the latter confined in a marginal series ventrad; meso-Eyes separated by a distance less than that between posterior ocelli; cheek, ventrad of eye, at greatest height exceeding length of third antennal segment, abruptly constricted throughout the caudal area by

the curvature of the occipital margin; thoracic vittæ abruptly termi-

	nated at transverse suture, the presutural area with no brownish
	vitte
	obtuse, resulting in a less marked constriction of the caudal area of cheek; thorax with vittee continued from postsutural to presutura area ————————————————————————————————
34.	Scutellum with two or more setulose, appressed hairs on dorsal margin
	of declivities adjacent the apical bristles
	adjacent the apical bristles
35.	Mesopleural series of bristles with one or more weaker intermediate pre
	dorsal bristles; markings on tergum 3 large, often fused mesad, ex
	tending along the caudal margin of tergum to lateral border of dor
	sumærea Zettersted: Mesopleural series of bristles with no intermediate predorsal bristles
	the intermission bare; markings of tergum 3 rarely fused mesad36
36.	Hind femur with the distal bristle of anterodorsal series situated at a
	lower (ventral) plane to those of the series; wings largely infus cated; cross veins clouded; basal sclerite of hypopygium shining. **nigriventris** Zettersted:
	Hind femur with the distal bristle of anterodorsal series situated in a
	continuous series with the remainder, not in a decidedly lower (ven tral) position; wings largely hyaline, slightly infuscated basad; cross
	veins clear; basal sclerite of hypopygium grayish pollinose37
37.	Presutural area of thorax with only a median vitta, the postsutura • area with three vitta, the sublaterals not extending cephalad beyond
	the transverse suture; scutellum entirely infuscated, not concolorous
	with mesonotum; proboscis with distal section noticeably shortened
	arenosa Ringdah
_	Presutural area of thorax with three vitte, median and sublaterals, the
	latter not foreshortened at transverse suture; scutellum concolorous with mesonotum; proboscis with distal section not abnormal in
38.	length
	teroventral surface, exceeding in length the apical setæ39
	Hind femur with a series of normal setulæ on proximal half of postero
20	ventral surface, none of which are longer than the apical setæ
39.	Processes of fifth sternum of abdomen sharply attenuated at apex; eyes large, when viewed in profile the ventral margin reaching to a level
	with oral vibrisse, thereby restricting the cheeks to narrow propor
	tions40
_	Processes of fifth sternum broad and rounded in outline toward apex
	not attenuated sharply: cheeks broad, higher than breadth of para-

	facials at base of antennæ; ventral margin of eyes not reaching a level with oral vibrissæ
40.	Abdomen silvery white pruinescent, with two small blackish marks on tergum 3 only argentiventris Malloch
	Abdomen grayish pruinescent, with small, paired, deep brownish spots on terga 3 and 4, the marks on tergum 4 more or less obscure. argentiventris var. occidentalis, n. var.
41.	Abdomen cinereous gray with two relatively small marks on terga 3 and 4; presutural acrosticals bristlelike but short; vibrissal area clothed with numerous short, stout setulæeretans, n. sp.
	Abdomen with tergal markings relatively large or conspicuous; presutural acrosticals setulose; vibrissal area clothed with fine setulæ42
42.	Scutellum, basal segment of hypopygium and terga 1+2 largely grayish pollinose; wings hyaline43
	Scutellum, basal segment of hypopygium and terga 1+2 largely blackish, subshining; wings infuscated at base44
43.	Mid and hind femora with a series of bristles on proximal half of posteroventral surface; eyes widely separated, distance greater than that between posterior ocelli inclusive, parafrontals not contiguous;
	tibiæ and tarsi usually yellowish
44.	Subcosta with a few setulæ on under surface proximad of humeral cross vein; hind tibia with 4 or 5 anteroventral bristles; humeral and notopleural callosities strikingly pale grayish pruinescent. **setinervis**, n. sp.*
_	Subcosta bare on under surface proximad of humeral cross vein; hind tibia with 2 or 3 anteroventral bristles,
45.	Hind femur with bristles on proximal half of posteroventral surface shorter than those on proximal half of posterior surface, not longer than breadth of femur; abdomen narrowly conical, third and fourth sterna longer than broad, clothed with short vestiture. **carbonella** Zetterstedt*
	Hind femur with bristles on proximal half of posteroventral surface longer than those on proximal half of posterior surface, the longest longer than breadth of femur; abdomen broadly conical, subovoid; third and fourth sterna broader than long, clothed with longish vestiture46
46.	Processes of fifth abdominal sternum with a highly polished apical process on inner margin; mid tibia with 1 or 2 well developed anterodorsal bristles, with no median posteroventral bristle. **computation** computation** comp

_	Processes of fifth sternum rounded at apex, with no highly polished attenuation on inner margin; mid tibia with anterodorsal bristles at
	most setulose, frequently absent
47.	Proboscis polished; fore tibia with no median posterior bristle; first
	abdominal sternum barenovæ-angliæ Malloch
	Proboscis lightly pollinose; fore tibia with a median posterior bristle
	first abdominal sternum with a few setulæalliterata, n. sp
48.	Mesopleural series of bristles with one or more weaker intermediate
	predorsal bristles49
	Mesopleural series of bristles with no predorsal bristle, the interspace
	bare
49.	Thorax with three distinctive broad bandlike vittæ; eyes with numerous
	hairs; calyptræ intensively yellow; scutellum with a noticeably pale
	area on discal surfacetrilineata, n. sp
	Thorax with no distinctive broad vittæ; eyes bare; calyptræ slightly
	tinged; scutellum entirely blackimitatrix Malloch
50.	Abdomen with a narrow brownish interrupted dorsocentral vitta; inner
	margins of markings on terga 3 and 4 divergent cephalad, the mark
	ings broadly separated; terga 1+2 grayish pruinescent with brown
	ish reflections, not blackened; calyptræ intensively yellowish; fronta
	vitta entire, distinctly separating the parafrontals; wings clear a
	baseincauta, n. sp
	Abdomen with no dorsocentral vitta; inner margin of markings or
	tergum 3 subparallel; terga 1+2 largely blackish or brownish, con
g 1	colorous with abdominal marks
51.	Thorax largely pale, grayish, with a broad, quadrate, light brownish spot between the dorsocentral bristles immediately caudad of trans
	verse suture; scutellum infuscated on basal half; presutural acrostic
	als stoutly developed, bristlelike but short; fifth tergum pale, gray
	ish, unmarked
_	Thorax largely blackish or deep brownish; markings obscured; pre
	sutural acrosticals setulose; fifth tergum with marks
52	Parafrontals with a continuous series of uniformly developed bristles to
	about level with anterior ocellus; processes of fifth sternum more of
	less reddish tinged along the inner margin; wings blackened basad
	fuscomarginata, n. sp
	Parafrontal bristles not continued in series to about level with anterio
	ocellus, the anterior pairs of bristles in series noticeably stoute
	developed than those situated caudad; processes of fifth sternum no
	reddish tinged along inner margin; wings at most brownish infus
	cated at base, not blackened5
53.	Parafrontals and parafacials in profile almost obliterated from view
	basal segment of hypopygium grayish pollinose; processes of fifth
	sternum not attenuated at apex; proboscis lightly pollinose.
	torreyæ Johannser
_	Parafrontals and parafacials readily recognized when viewed in profile
	at broadest distance equal to half breadth of third antennal seg

	ment; basal segment of hypopygium blackish, shining; processes of fifth sternum attenuated at apex; proboscis glossy, polished.
	crassiventris, n. sp.
54.	
	size to the first pair of parafrontal bristles55
	Head with inner pair of vertical bristles fine and slender, not equal in
	development to first pair of parafrontal bristles60
55.	Hind femur with a series of longish bristles on posteroventral surface;
	grayish brown species
	Hind femur at most with a series of setulæ on posteroventral surface;
	grayish white species57
56.	Ocellar bristles as long and as robust as first pair of dorsocentral
	bristles; eyes separated by a distance greater than half that between
	first pair of dorsocentral bristles; mid femur with bristles on basal
	third of posteroventral surface fine and setuloseacuticornis Malloch
	Ocellar bristles shorter and weaker developed than first pair of dorso-
	central bristles; eyes separated by a distance about equal to half
	that between first pair of dorsocentral bristles; mid femur with at
	least 2 or 3 bristles on basal third of posteroventral surface strong
	and bristlelikesurda Zetterstedt
57.	Eyes separated at middle of frons by a distance fully equal to length
	of third antennal segment; thorax with three intensive, brown vittæ;
	scutellum with brownish marks laterad58
	Eyes separated at middle of frons by a distance less than length of
	third antennal segment; thorax with no well defined vittæ and lateral
	marks on scutellum; processes of fifth sternum entirely blackish59
58.	Cheek ventrad of eye not higher than breadth of third antennal seg-
	ment; frontal vitta black, opaque; fore tibia with a posterior bristle
	at middle
	Cheek ventrad of eye higher than breadth of third antennal segment;
	frontal vitta whitish pruinose; fore tibia with no posterior bristle
	at middleargenticeps Malloch
59.	Third antennal segment three times as long as wide, reaching to a
	level below that of ventral margin of eye; parafrontals at base of
	antennæ noticeably prominent, protruding beyond a level with the
	base of vibrissæ
	Third antennal segment not more than twice as long as wide, not reach-
	ing to level of ventral margin of eye; parafrontals not prominent
	nor protruding, not broader than width of third antennal segment.
0.0	cana, n. sp.
60.	Mid femur with two stout erect bristles at base of posteroventral sur-
	face, in addition to the bristle at base of ventral surface61 Mid femur with a series of four or more bristles on proximal half of
	posteroventral surface, if less the bristles are not spinelike
61	Plackish species; scutellum and basal segment of hypopygium shining,
61.	black; wings intensively infuscatedbisetosa, n. sp.
	black, wings intensively infuscated

_	Grayish species; scutellum grayish tinged, basal segment of hypopygium
	largely grayish pollinose; wings tinged, notably adjoining the
	veinsbisetosa var. pruinella, n. var.
62.	Hind tibiæ, at least, yellowish, occasionally infuscated
	Hind tibiæ blackish64
63.	Scutellum with a few fine appressed setulæ on dorsal margin of lateral
	declivities adjoining apical bristles; parafrontal bristles not con-
	tinued in series caudad to about level with anterior ocellus; processes
	of fifth sternum truncate at apex; abdominal markings not well
	definedrufitibia Stein
	Scutellum with no appressed setulæ on upper margin of lateral declivi-
	ties adjacent the apical bristles; parafrontal bristles continued in
	series caudad to a level approximating that of anterior ocellus; proc-
	esses of fifth sternum not truncate at apex; abdominal markings sharply defined
64.	
UT.	of posteroventral surface, the longest of which exceeds in length that
	of apical setæ on posteroventral surface
	Hind femur with no series of longish bristles on proximal two-thirds
	of posteroventral surface, the longest of which does not exceed the
	length of apical setæ72
65.	Eyes separated at narrowest by a distance fully equal to half that be-
	tween first pair of dorsocentral bristles; parafacials at base of
	antennæ as wide as length of second antennal segment.
	surda Zetterstedt
	Eyes separated at narrowest by a distance less than half that between
	first pair of dorsocentral bristles; parafacials at base of antenna
cc	not as wide as length of second antennal segment 66
66.	Hind femur with bristles on proximal half of anteroventral surface fully as long as those on distal half
	Hind femur with bristles on proximal half of anteroventral surface
	shorter than those on distal half67
67.	Third abdominal tergum with large black trapezoidal markings whose
	proportions largely constrict the lighter pollinose areas to insignifi-
	cance, frequently the entire tergum together with terga 1+2 almost
	entirely blackened; supraalar bristle with no short duplicating bristle
	immediately caudad; costal vein with a series of prominent though
	not long setulæ on proximal half; scutellum with 2 or 3 appressed
	setulæ on dorsal margin of lateral declivities adjacent the apical
	bristlespluvialis, n. sp.
	Tergum 3 with markings longer than average breadth, confined to mesal
	third of tergum, the tergal surface largely grayish white pruinescent;
	supraalar bristle with a weak but distinctive duplicating bristle im-

68. Scutellum with two fine appressed setulæ on dorsal margin of lateral declivities adjacent apical bristles; hind femur with a series of long fine bristles on proximal half of posteroventral surface, the longest exceeding in length the width of femur where situated; hind tibia with apical anterodorsal bristle weakly developed. baltica Ringdahl - Scutellum with no fine appressed setulæ on dorsal margin of lateral declivities adjacent apical bristles; hind femur with a series of short bristles on proximal half of posteroventral surface, the longest of which are not longer than breadth of femur where situated; apical anterodorsal bristle of hind tibia well developed69 69. Halteres blackish; mesopleural series of bristles with a weaker intermediate predorsal bristle; arista pubescent, hairs longer than basal diameter of aristacarbonella Zetterstedt Halteres yellow; mesopleural series of bristles with no weaker predorsal bristle, the intermission bare; arista short pubescent, hairs 70. Processes of fifth sternum tapering apicad; fore tibia with no posteroventral bristle at middle; caudal segments of abdomen compressed dorsoventrally; second and third sterna longer than wide; hind femur with a preapical posterodorsal bristle in addition to the normal dorsal bristle; wings blackened basadgibsoni Malloch Processes of fifth sternum broad and truncate toward apex; fore tibia with a median posteroventral bristle; caudal segments of abdomen compressed laterally; second and third sterna as broad as long71 71. Wings tinged with infuscation; thorax and coxe brownish black, face brownish pollinose; fifth sternum deeply incised, the incision reaching to middle of platecontractifrons var. fumipennis Zetterstedt Wings hyaline throughout; thorax and coxe lightly grayish white pollinose; face grayish pollinose; fifth sternum shallowly incised, the incision reaching to one-third length of platealticola Malloch 72. Processes of fifth sternum clothed with coarse long black bristles on distal region; mid femur with one basal bristle and a series of 5 or 6 short weak setulose posteroventral bristles on proximal half, the latter not longer than half breadth of femur where situated; eyes separated by a distance greater than breadth of third antennal segment. pulchra, n. sp. Processes of fifth sternum not clothed with long black bristles on distal half, at most with a few sparsely set bristles; mid femur with a series of 3 or 4 bristles, the longest of which are at least about equal to breadth of femur where situated; eyes separated at narrowest by a distance not greater than breadth of third antennal segment73 73. Abdomen with expansive black subtriangular markings on terga 3 and 4, whose average breadth is greater than length of tergum; basal sclerite of hypopygium black and shining; fifth sternum subshining;

wings blackened basad74

	Abdomen with tergal markings confined to dorsum, whose average
	breadth is not greater than length of tergum; basal sclerite of
	hypopygium lightly grayish white pollinose; fifth sternum opaque;
	wings hyaline, at most lightly infuscated at base75
74.	
	Calyptræ whitish, tinged with yellowmagnipunctata Malloch
75.	Scutellum with a few appressed setulose hairs on dorsal margin of
	lateral declivities adjacent apical bristles; sternopleural bristles 1: 1.
	reflecta, n. sp.
	Scutellum with no appressed setulose hairs on dorsal margin of lateral
	declivities adjacent apical bristles; sternopleural bristles, 1: 2.
	parvimaculata Stein
	Females
1.	Postsutural dorsocentral bristles usually four pairs2
	Postsutural dorsocentral bristles usually three pairs 43
2.	Mid tibia with a median ventral bristle3
	Mid tibia with no median ventral bristle 8
3.	Hind femur with a series of two or more bristles on proximal half of
υ.	posteroventral surface; with the anteroventral bristles continued in a
	distinctive though weaker series to base of femur4
	Hind femur with no series of bristles on proximal half of posteroven-
	tral surface, the shortest of which being longer than the apical setæ
	on posteroventral surface
4.	Mesopleural series of bristles with one or more weaker intermediate
	predorsal bristles; fore tarsus with segments 3 and 4 broadened,
	similar to segment 5 and dissimilar to segment 1; lower calyptra
	not restricted in size; costa with no series of prominent setulæ on
	proximal half
	Mesopleural series of bristles with no weaker predorsal bristles, the
	intermission bare; fore tarsus with segments 2 and 3 not broadened,
	similar to segment 1 and dissimilar to segment 5; lower calyptra nar-
	rower at base than greatest length, restricted in size; costa with a
	series of prominent setulæ on proximal halfobsoleta Malloch
5.	Oral margin protruded slightly beyond a level with base of antennæ
	when viewed in profile
	Oral margin not protruded beyond a level with base of antennæ when
	viewed in profile7
6.	Scutellum with appressed setulose hairs on dorsal margin of lateral
	declivities adjacent apical bristles; mesopleural series of bristles with
	a weaker intermediate predorsal bristle; sternopleural bristles, 1: 2.
	hyperborea Boheman
_	Scutellum with no setulose hairs on dorsal margin of lateral declivities
	adjacent apical bristles; mesopleural series of bristles with no pre-
	apical bristle, the intermission bare; sternopleural bristles, 1:1.
	subrostrata Stein

7. Costa with a few strong accessory setulæ on dorsal surface adjacent the vein R. 1 (wing viewed in a horizontal position); lower calvptra reduced in size, very little larger than upper calvptra; scutellum with appressed setulose hairs on dorsal margin of lateral declivities adjacent apical bristles; proboscis lightly pollinosemelanosoma, n. sp. Costa with no accessory setulæ on dorsal surface adjacent vein R, 1 (wing viewed in a horizontal position); lower calyptra of normal appearance, larger than upper calyptra; scutellum with no appressed hairs on dorsal margin of lateral declivities adjacent apical bristles; proboscis polishedsectata, n. sp. 8. Frontal vitta with frontal triangle polished and glossy ______9 9. Wings conspicuously clouded at cross veins; hind femur with the distal bristle of anterodorsal series situated at a lower (ventrad) plane to those of the series; eyes separated at middle of frons by a distance about equal to greatest breadth of eve when viewed from in front; thorax cinereous gray; abdomen entirely glossy and polished; pro-Wings with cross veins clear; hind femur with the distal bristle of anterodorsal series in the same plane as those of series; eyes separated at middle of frons by a distance greater than maximum breadth of eye when viewed from in front; thorax grayish black; proboscis highly polished ______10 10. Halteres blackish; abdomen blackish, shining, unmarked, with trace of Halteres, yellowish, sometimes reddish brown; abdomen lightly grayish pruinescent, subshining, with traces of brownish markings. aerea Zetterstedt 11. Hind femur with bristles or bristly hairs on basal half of posteroventral surface longer than apical setæ on posteroventral surface......12 Hind femur with no bristles on basal half of posteroventral surface; bristly hairs if present, not longer than apical setæ on posteroventral surface 31 12. Presutural acrostical bristles stoutly developed, bristle-like, stronger developed than scutellar setulæ; median series of fine bristly hairs on proximal half of posterior surface of hind femur reduced to 2 or 3 in number ______13 Presutural acrostical bristles setulose, not stronger developed than 13. Mid tibia with one or two longish anterodorsal bristles; mid femur with a short series of bristles on proximal half of anteroventral surface, the longest of which are equal to those on anterior surface......14 Mid tibia with no anterodorsal bristles, at most a small setulose bristle present; mid femur with, at most, a series of weak bristles on proximal half of anteroventral surface, the longest of which are shorter than those on anterior surface ______15

14.	Blackish species, subshining; with slight grayish brown pruinescence;
	mesonotum with vittæ faint and obscure; abdomen with tergal mark-
	ings small and indefinite; cheeks about as broad as parafacials at
	base of antennætetrachæta Malloch
	Pale, grayish species, opaque; with dense whitish gray pruinescence;
	mesonotum with three distinct brown vittæ; abdomen with large,
	brownish tergal markings and dorsocentral vitta; cheeks broader than
	parafacials at base of antennæ
15.	Eye nearly as high as length of fore tibia; cheeks about as broad as
10.	
	breadth of third antennal segment; fore tibia with no median pos-
	terior bristleargentiventris var. occidentalis, n. var.
	Eye much shorter in height than length of fore tibia; cheeks much
	higher than breadth of third antennal segment; fore tibia with a
	median posterior bristlecretans, n. sp.
16.	Head, thorax and abdomen densely yellowish gray pollinose, the latter
	ochreous; thorax and abdomen with no marksnarina Walker
—	Thorax and abdomen at least with markings, or, blackish, shining17
17.	Scutellum with setulose hairs on dorsal margin of lateral declivities
	adjacent apical bristles
_	Scutellum with no setulose hairs on dorsal margin of lateral declivities
	adjacent apical bristles19
18.	Oral margin protruded slightly beyond a level with base of antennæ
	when viewed in profile; antennæ separated at base by a large facial
	prominence; proboscis polished; large species, 6-7 mm.

	Eyes bare; abdomen with no marksextensa Malloch
23.	Mesopleura and scutellum largely blackened; mesonotum with no trace of vittæ; parafrontals entirely brownish infuscatedalberta, n. sp.
	Mesopleura and scutellum largely grayish pruinescent; mesonotum largely grayish with brownish vittæ; parafrontals grayish pruinescent
24.	Ovipositor with spinules on anal plates; frontal vitta wider than distance between oral vibrissæ, about three times as wide as each parafrontal
_	Ovipositor with fine setulæ on suranal plates; frontal vitta narrower than distance between oral vibrissæ, about equal to twice breadth of each parafrontalsetilamellata, n. sp.
25.	Subcostal vein with a few setulose hairs on under surface proximad of humeral cross vein; terga 3, 4, and 5 with paired brownish marks on lateral (ventral) areas, separated from the normal dorsal markings; parafacials at base of antennæ equal to half diameter of eye immediately caudad of this position
	Subcostal vein with no setulose hairs on under surface proximad of humeral cross vein; terga 3, 4, and 5 with no lateral marks other than those that are continuous with those on dorsum; parafacials at base of antennæ less than half diameter of eye immediately caudad of this position26
26.	Ovipositor armed with spinules on anal plates; calyptræ white
27.	Mid femur with a series of posteroventral bristles; proboscis pollinose; first abdominal sternum bare
-	Mid femur with no posteroventral bristles; proboscis polished, shining; first abdominal sternum with a few setulæplacida, n. sp.
28.	Hind femur with a complete series of strong anteroventral bristles; abdomen with conspicuous brownish patches on ventral aspect of
	terga
29.	abdomen with no brownish areas on ventral aspect of terga29 Proboscis pollinose; first abdominal sternum with a few setulæ; thorax with three heavy dark brown vittæ and a broad fuscous area immedi-
	ately caudad of transverse suture between the dorsocentral bristles. alliterata, n. sp.
_	Proboscis polished; first abdominal sternum bare; thorax with at most a well marked median vitta, the sublaterals obscure

HUCKETT: LIMNOPHORA

0.0	mu:
30.	Tibiæ more or less yellowish; cheek higher than breadth of parafacial
	at base of antennæ, the parafacials markedly restricted ventrad; fore
	tibia with no median posterior bristlerufitarsis Stein
	Tibiæ entirely black; cheek not higher than breadth of parafacial at
	base of antennæ, parafacials at narrowest as broad as width of third
	antennal segment; fore tibia with one or more median posterior
	bristlesincauta, n. sp.
31.	Mesopleural series of bristles with a weaker intermediate predorsal
	bristle32
	Mesopleural series of bristles with no predorsal bristle, the intermission
	bare34
32.	Thorax with three narrow distinctive brownish vittæ between the dorso-
	central bristles; calyptræ yellowishtrilineata, n. sp.
	Thorax with a single vitta between the dorsocentral bristles, at most;
	calyptræ whitish33
33.	Scutellum with appressed setulose hairs on dorsal margin of lateral
	declivities adjacent apical bristles; ovipositor with fine spinules on
	subanal plate; blackish speciesaddicta, n. sp.
	Scutellum with no appressed setulose hairs on dorsal margin of lateral
	declivities adjacent apical bristles; ovipositor with fine setulose hairs
	on subanal plate; grayish speciesimitatrix Malloch
34.	Presutural acrosticals irregularly paired, bristlelike, stronger developed
or.	than the scutellar setulæ; frontal vitta almost obliterated by the pro-
	nounced ocellar triangle, the latter is densely pollinose, concolorous
	with parafrontals and reaches to base of antennæ; calyptræ white.
	brevicornis Malloch
	Presutural acrosticals setulose, not stronger developed than scutellar
	setulæ 35
25	Discal area of mesonotum with dense seal brown infuscation covering
35.	
	uniformly the postsutural and presutural regions; mesopleura pearle-
	asceous gray; parafrontals seal brown infuscated; frontal vitta
	rufous cephalad; mid femur with posteroventral bristles setulose;
	proboscis pollinosetorreyæ Johannsen
	Discal area of mesonotum vittate, not entirely infuscated; proboscis
	polished, glossy36
36.	Scutellum with appressed setulose hairs on dorsal margin of lateral
	declivities adjacent apical bristles; hind tibia with one anterodorsal
	bristle; ovipositor with fine setulæ on anal plates.
	denudata Holmgren
_	Scutellum with no appressed setulose hairs on dorsal margin of lateral
	declivities adjacent apical bristles; hind tibia with two or more
	anterodorsal bristles
37.	Ovipositor with spinules on anal plates38
_	Ovipositor with fine setulæ only on anal plates40
38.	Mid tibia with 2 or more well developed anterodorsal bristles; wings

	infuscated, cross veins faintly clouded; costa with a short series of stoutly developed setulæ proximad of costal thorn, the setulæ fully
	as long as width of costasospita, n. sp.
	Mid tibia with at most one anterodorsal bristle; wings clear, hyaline,
	cross veins clear; costal setulæ proximad of costal thorn weakly de-
	veloped
39.	Pale grayish species; lunule at base of antennæ silvery pruinescent;
	first abdominal sternum with a few hairs or setulæ; parafrontals with
	brownish infuscation confined to a narrow border adjacent frontal
	vittaplacida, n. sp.
	Dark grayish species; lunule at base of antennæ brownish black prui-
	nescent; first abdominal sternum bare; parafrontals broadly brown-
	ish infuscated to margin of eye
40.	Sternopleura with a noticeable tuft of bristles ventrad; parafacials
10.	broader and cheeks higher than length of third antennal segment.
	pulvicrura, n. sp.
	Sternopleura with bristles not tufted ventrad, arranged more or less in
	series; parafacials and cheeks at narrowest dimensions not more than
	length of third antennal segment41
41.	Parafacials at greatest breadth and cheeks at greatest height about
41.	equal to length of third antennal segment; calyptræ intensively yel-
	lowish; bucce with a single series of sparsely set bristles along ventral marginincauta, n. sp.
	Parafacials at greatest breadth and cheeks at greatest height not equal
	to length of third antennal segment; calyptræ, at most, tinged;
	bucce with a series of closely set setulæ and bristles along ventral
	margin42
42.	Mid tibia with one or more median anterodorsal bristles; m-cu cross
T 2.	vein clouded; abdomen subshining, highly pruinescent, with large
	broad subtriangular marks on terga 3 and 4 that extend ventrad
	along the caudal margin of each segment; scutellum with blackish
	areas at basal angles fuscomarginata, n. sp.
_	Mid tibia with no median anterodorsal bristle; m-cu cross vein clear;
	abdomen densely pollinose, opaque; with comparatively small brown-
	ish marks on terga 3 and 4, restricted to dorsum; scutellum entirely
	grayish pollinose
43.	Tibiæ yellowish 44
	Tibiæ blackish 45
44.	Scutellum with appressed setulose hairs on dorsal margin of lateral
	declivities adjacent apical bristles; mid tibia with no anterodorsal
	bristle; fore tibia with no median posterior bristlerufitibia Stein
_	Scutellum with no appressed setulose hairs on dorsal margin of lateral
	declivities adjacent apical bristles; mid tibia with 1 or 2 anterodor-
	sal bristles; fore tibia with one posterior bristlesuspecta Malloch

45.	Mesonotum, scutellum and from largely covered with deep seal brown
	coloration; humeral callosity with one bristle (the inner bristle
	weakly developed, setulose); proboscis pollinose, not shining.
	torreyæ Johannsen
	Mesonotum, scutellum, and from largely grayish, at most the former
	vittate, and the scutellum with spots at basal angles; humeral cal-
	losity with two bristles46
46.	Ovipositor with spinules on anal plate
10.	Ovipositor with fine hairs or setulæ on anal plates; no spinules49
4.7	
47.	Scutellum with preapical bristles well developed, in size at least as
	robust as basal bristles; mid femur with one or two strong erect
	bristles on basal third of posteroventral surfacebisetosa, n. sp.
	Scutellum with no noticeable preapical bristles, if present, they are
	weaker than the basal bristles; with setulose hairs on dorsal margin
	of lateral declivities adjacent the apical bristles48
48.	Mid femur with a series of bristles on proximal half of posteroventral
	surface; fore tibia with a median posterior bristle; m-cu cross vein
	clearsurda Zetterstedt
	Mid femur without, or with but one or two widely separated bristles
	on proximal half of posteroventral surface; fore tibia with no pos-
	terior bristle at middle; m-cu cross vein cloudy.
	acuticornis Malloch
49.	Costa with a series of strong erect setulæ between the junctures of
	auxilliary and humeral cross vein with costa, the setulæ longer than
	diameter of costa; scutellum with setulose hairs on dorsal margin
	adjacent apical bristles; vertical bristles of head separated by a dis-
	tance about equal to that between first pair of dorsocentral bristles.
	pluvialis, n. sp.
	Costa with no series of prominent setulæ between the junctures of aux-
	iliary and humeral cross vein with costa; scutellum with no setulose
	hairs on dorsal margin of lateral declivities adjacent apical bristles;
	vertical bristles of head separated by a distance less than that be-
	tween first pair of dorsocentral bristles50
50.	Mid tibia with no anterodorsal bristle; mid femur with 1 or 2 bristles
	on proximal third of posteroventral surface; proboscis pollinose;
	scutellum entirely pale grayish
	Mid tibia with 1 or 2 anterodorsal bristles; mid femur with a series of
	at least 3 or 4 bristles on proximal half of posteroventral surface;
	proboscis shining; scutellum with trace of fuscous areas at basal
	angles52
51	
51.	Scutellum with setulose hairs on dorsal margin of lateral declivities
	adjacent apical bristles; cheeks at narrowest height about one fourth
	that of eye; fore tibia with no median posterior bristle; fore coxe
	with the inner series of bristles on anterior surface not robust.
	reflecta, n. sp.

alticola Malloch

Scutellum with no setulose hairs on dorsal margin of lateral declivities adjacent apical bristles; cheeks at narrowest height about one sixth that of eye; fore tibia with 1 or 2 median posterior bristles; fore coxe with the inner series of bristles on anterior surface robustly developed _____parvimaculata Stein 52. Hind femur with a series of longish bristles restricted to median third of posteroventral surface, the proximal third devoid of bristles. gibsoni Malloch Hind femur with, at most, a series of longish setulæ on proximal third of posteroventral surface, the median third with no longish bristles...53 53. Width of parafacials at base of antennæ, when viewed in profile, not less than one third the diameter of eye immediately caudad of this position; cheeks about as high as one third that of eye. incauta, n. sp. Width of parafacials at base of antennæ not equal in breadth to one third the diameter of eye immediately caudad of this position; cheeks not as high as one third that of eye54 54. Parafrontals with seal brown infuscation along the border of frontal vitta; frontal vitta and frontal triangle with seal brown pruines-Parafrontals entirely slate gray pruinescent, with no brownish infuscation along the margin of frontal vitta; frontal vitta and frontal 55. Both upper and lower calyptra intensively yellowish; parafacials at narrowest breadth narrower than width of third antennal segmentanthrax Bigot Calyptræ yellowish tinged; parafacials at narrowest breadth at least as wide as third antennal segmentmagnipunctata Malloch 56. Hind femur with anteroventral series of bristles continued to base; thorax with a median vitta. contractifrons var. fumipennis Zetterstedt Hind femur with anteroventral series of bristles confined to distal twothirds, not continued to base; thorax with no median vitta.
